Abstract -- This paper presents an innovative face recognition method which is based on combination of graph isomorphism technique and Gabor wavelet. Here features are selected. Then are of the determines the distance between these features in the face image. The algorithm applies Gabor wavelet on the selected features. Algorithm takes into account Gabor coefficient as well as Euclidean distance between features for face recognition. Brightness normalized and non-normalized face images are given for face recognition to demonstrate that the normalized faces can improve the recognition rate.

Keywords- Face detection, graph isomorphism , Face recognition, brightness normalization, , gabor wavelet.

I. INTRODUCTIO

The choice of the object representation is crucial for an effective performance of cognitive tasks such as object recognition, fixation, etc. Face recognition is in example of advanced object recognition. In this paper we demonstrate the use of Gabor wavelets are graph isomorphism for efficient face recognition. Face recognition is influenced by several factors such as shape, reflectance, pose, occlusion and illumination which make it even more difficult. Many b ign tness normalization algorithms have been presented before [1, 2, 3, and 4]. But they are computationally expensive. Paper introduces the simple preprocessing technique such as brightness normalization to improve face recognition rate. Paper wants to introduce combination of Gabor wavelets and graph isomorphism for an efficient face recognition system simulating human perception of objects and faces. A face recognition system could greatly aid in the process of searching and classifying a face database and at a higher level help in identification of possible threats to security. The purpose of the study is to demonstrate that it is technically feasible to scan pictures of human faces and compare them with ID photos hosted in a centralized database using combination of Gabor wavelets and graph is properly in the objective of the face normalization is to reduce the effect of useless, interferential and regulation such as background so as to enhance the recognition process. Igorithms of face recognition. First graph isomorphism and second combination of graph isomorphism and Gabor wavelet. Algorithm assumes that the face is already detected. Then manually select features such as left eye ball centre and right eye ball center, nose tip and left and right corners of the aph isomorphism finds Euclidean distance between features for face recognition. Graph rp ism + Gabor wavelet algorithm takes Gabor representation of face image. Now along with Gabor pefficient take Euclidean distance between features as well for face recognition. Compare result of two proposed algorithms. The experiments carried out showed that the proposed algorithm can effectively and efficiently recognize the face images. The experiments showed that after the brightness normalization the face recognition rate was improved by about 4 to 5 percent for the combined method on the ORL face image database.

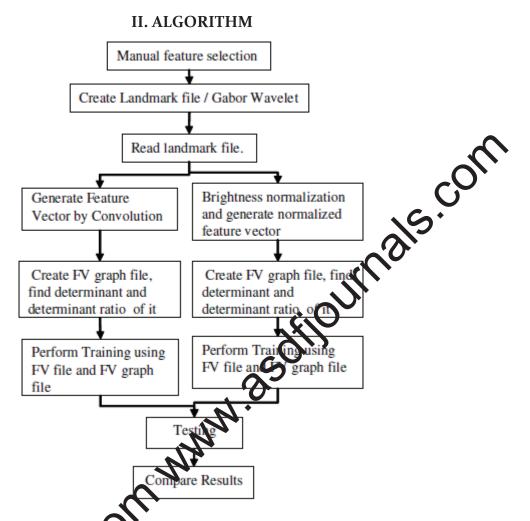

Figure 1 flowchast of the combined face recognition algorithm.

III. FACE CRAPH CREATION & GRAPH ISOMORPHISM

All 5 features (left eye ball and right eye ball center ,nose tip and left and right corners of mouth) are manually selected and (heir coordinates(x,y) are stored in a file called landmarksDB. Connect these five features by lines to Real landmark file. Brightness normalization and generate normalized feature vector Testing Compare results Create FV graph file, find determinant and determinant ratio of it Perform Training using FV file and FV graph file Create FV graph file, find determinant and determinant ratio of it Create Landmark file / Gabor Wavelet Manual feature selection Generate Feature Vector by Convolution each other and graph is form called face graph. Create adjacents matrix called graph file FV_graph_file to store Euclidean distance between these graph prints/podes. The distance of point from itself is taken as o. Graph isomorphism technique is used for face ecognition. Iso means same and morphism means structure. Algorithm compares 2 face graph to check whether they are having same structure.

IV. GABOR WAVELET AND BUNCH GRAPH CREATION

The Gabor Transform is one of the most famous image processing tools that is used to capture spatial and orientation details [5, 6]. The Gabor wavelet representation facilitates recognition without correspondence because it captures the local structure corresponding to spatial frequency, spatial localization, and

orientation selectivity. As a result, the Gabor wavelet representation of face images should be robust to variations due to illumination and facial expression changes.

The Gabor wavelet is used here in order to obtain a "Gabor representation" of the image that can hopefully capture class-specific information that will help enhance recognition rates. The representation of images by Gabor wavelets is chosen for its biological relevance and technical properties. The Gabor wavelet approach is fundamentally different from others because it recognizes faces by comparing their parts instead of performing Holistic image matching. The features are represented by Gabor jets. The jets are extracted from images with manually selected landmark locations. The model jets are then collected in a data structure called a bunch graph. The bunch graph has a node for every landmark on the face. Every n collection of model jets for the corresponding landmark. The bunch graph serves as a database q descriptions that can be used to locate landmarks in novel imagery. The algorithm first find Undmark locations on the images that correspond to facial features such as the eyes, nose, and more than uses Gabor wavelet convolutions at these points to describe the features of the landmark. A fact represent each image. The face graph nodes are placed at the landmark locations, and the hode contains a Gabor jet extracted from that location. The similarity of two images is a function of the corresponding face graphs. Novel jet contains frequency information about the local image region around their extraction point. The landmarks are characterized by two things, a location in the image and a Gabor jet extracted from that location. After the face graph is created, the image is discarded, and the face graph becomes the internal representation of that image. The face graph occupies less men or than the image, and computing entire database of faces can be kept in memory, and new images can be identified rapidly. The algoriuming pre-computed wavelet mask. Each mask is a two dimensional array that is used as a lookup table for wavelet values during condution. The masks are centered over the correct location in the image, and each corresponding value is multiplied and added to the sum. To compute both the real and imaginary part of the wave exit is necessary to convolve the image with two masks that are out of phase by p /2, corresponding to the use of sine and cosine in the wavelet transform.

There are five parameters that control the waveled

- 1 q specifies the orientation of the wavelet. This parameter rotates the wavelet about its center. The orientation of the wavelets dictates the angle of the edges or bars for which the wavelet will respond.
- 2 l .specifies the wavelength of the cosine wave, or inversely the frequency of the wavelet. Wavelets with a large wavelength will respond to gradual changes in intensity in the image.
- 3._ Specifies the phase of the inusoid. Typically Gabor wavelets are based on a sine or cosine wave. In case of this algorithm, cosine wavelets are thought to be the real part of the wavelet and the sine wavelets are thought to be the imaginary part of the wavelet. Therefore, a convolution with both phases produces a complex coefficient.
- 4. _ specifies the radius of the Gaussian. This parameter is usually proportional to the wavelength.
- 5. specifies the aspect ratio of the Gaussian. There are 80 Gabor filters and each will result in image, giving a total of 80 images. The images are then separately converted to vectors. The vectors are classified as train and est vectors. The train vectors are used to train the classifier. Test vectors are submitted to the classifier for hypothesis. The classifier uses Euclidean distance as a measure for finding match.

Algorithm: Gabor wavelet and creation of bunch graph

1. Algorithm uses manually selected landmark locations to produce the bunch graph. The manually selected landmark locations are collected by a tool, with a graphical user interface, that allows a user to select points

in an image that correspond to landmarks such as left eye, right eye, tip of the nose, left and right corner of the mouth. Save this file as landmarks file.

2. Generate Gabor wavelet with parameter as

```
sz_factor = 4,
lamda_param_set = {4, 4_2, 8, 8_2, 16},
Theta_set = {0, / 8 p, 2 / 8 p, 3 / 8 p, 4 / 8 p, 5 / 8 p, 6 / 8 p, 7 / 8 p},
phi_param_set = {0, p/2}.
80 Gabor wavelet are generated save this file as gabor_wavelet_profile.
```

- 3. Perform convolution of each feature with Gabor filters and save coefficient (jet) in file FV_file. Gabor jets, in this case referred to as model jets. The jets are extracted from images with manually selected landmark locations. A bunch graph is created by collecting model Gabor jets for every facial landmark. The model jets are then collected in a data structure called a bunch graph. The bunch graph has a node to every landmark on the face. Every node is a collection model jets for the corresponding landmark. The bunch graph serves as a database of landmark descriptions that is used to locate landmarks in novel in agery.
- 4. Gabor wavelet algorithm computes the similarity of two images. After the algorithm has created a face graph for two images, their similarity can be computed. Gabor jets are compared using Euclidean distance.

V. GABOR WAVELET + GRAPH ISOMORPHO (COMBINED) FACE RECOGNITION ALGORALHM

- 1. Read the feature vector file FV_file and graph file FV_graph file.
- 2. Train vectors first by FV_file and then by FV_grapt.
- 3. Give the test vector to the classifier. Classifier compares 2 vectors and chooses minimum Euclidean distance as a measure for recognition

VI Brightnes (Normalization Algorithm (B Norm)

The face images captured at different times or positions often have different brightness. These commonly affect the recognition significants. In order to reduce the affection of the brightness, we used brightness normalization method to the image have the same mean and the same variance value which is as follows.

- 1. Mean center the pixel values in the source image.
- 2. Linearly sproots the edges of the source image across a 30 pixel border.
- 3. Normalize the contrast of the new image with histogram equalization.
- The edge of the image is smoothed to reduce its effect in frequency space. Pixels greater than 30 pixels apart from the edge are not modified. This smoothes the image edge from actual pixel values in the center of the image to zero at the edge of the image. The algorithm then performs contrast and brightness normalizations.

VII. EXPERIMENTAL RESULTS

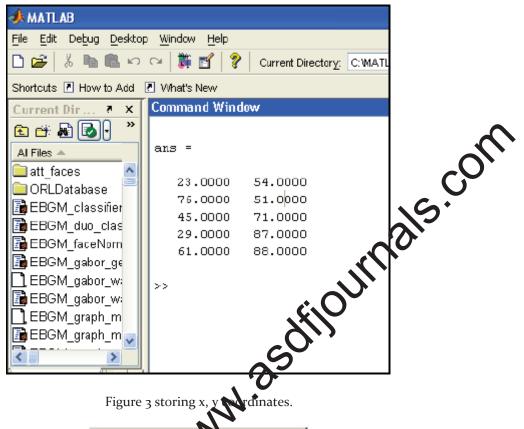

To verify the proposed algorithm, it was implemented and experiments were conducted. In the experiments, original images of ORL database were used. Figure 2 shows experimental result of feature selection. Figure 3 shows result of x and y coordinates for selected features. Figure 4 shows result of face graph creation. Figure 5 shows preprocessing result. Figure 6 shows result of brightness normalization. Figure 7 shows adjacency matrix. Figure 8 shows 80 Gabor wavelet. Algorithm used 400 images of 40 persons. In the experiments, first normalized the image by the method presented in this paper. Then to demonstrate that the normalization algorithm can really improve the face recognition rate, we carried comparison experiments of face recognition with and without face normalization. The face image trained and recognized based on method of graph isomorphism and Gabor Wavelet + graph isomorphism face recognition method. Algorithm used 1 to 10 images of a person to train and used the other remaining as well as all images for testing. The correct recognition rate of graph isomorphism is given able 1 and recognition rate of graph isomorphism+ Gabor wavelet is given in table 2. The tables re graph isomorphism + Gabor wavelet+ B NORM can improve the recognition rate of fac

VII. CONCLUSION

This paper presented a novel algorithm for face recognition which combines a aph isomorphism technique and Gabor wavelet. Algorithm was implemented and its performance ified, which demonstrated that this method can be effectively used along with brightness normalization improve recognition rate.
